

py-dimensional-analysis

1 py-dimensional-analysis

This Python package addresses physical dimensional analysis. In particular, `py-dimensional-analysis` calculates from a given system of (dimensional) variables those products that yield a desired target dimension.

The following example shows, a (single) relation between mass, force, and time produces length.

```
import danalysis as da
import danalysis.standard_units as si

r = da.solve({ 'a':si.M, 'b':si.F, 'c':si.T}, si.L)
print(r)
#Found 1 variable products of dimension L:
# 0: a**-1*b*c**2
```

This library is based on [Szi07] but also incorporates ideas from [San19, Son01].
